Some are just there to aid you the programmer when debugging. Although such procedures are not shown in the book they will help you to understand the book's ideas better. To start a programming flow you need to define the main part of a program. This is done when you declare variables and initialize them before or after the flow is started. Such variables are called Program State. The state of the program for a single procedure is called the procedure state. Such a procedure is shown in the Figure below. There are three major parts to the flow of a procedure, called a task. These are the input, output and the operations. Inputs are the data required to run the procedure. Outputs are the data to be used when run the procedure. Operations are the instructions. The diagram above also shows that a procedure can have multiple tasks and that any one of the tasks can be the one that is entered to. For example if a program is started with one task and then moved to a different task program flow would be interrupted. To save and resume a program flow such as in the example above the procedure should be saved. This is done when the procedure state is saved and its time to resume the program flow. In the figure above the procedure is called 1 from now on. The procedure's state is saved in a PSS (Program state) file. When the flow is resumed the state is loaded and the program goes on.
